Tennis Analysis

This notebook evaluates the three research goals:

1. How important is ranking for match outcomes?
2. Do players perform differently depending on the surface?
3. Which player characteristics are associated with winning matches?

The analysis uses:

- `data/matches_clean.csv`
- `data/stats_clean.csv`
- `data/top20_players_raw.csv`

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.ticker as mtick
import matplotlib.colors as mcolors
# import of CSV files
matches = pd.read_csv("data/matches_clean.csv")
stats = pd.read_csv("data/stats_clean.csv")
players = pd.read_csv("data/top20_players_raw.csv")
```

Data quality inspection

Before proceeding to the main analysis, we inspect the cleaned data for any remaining issues:

- verify the number of missing values
- check for duplicate matches
- identify any rows with incomplete information

This ensures the dataset is reliable for the research questions.

```
# Basic data checks
print("\nMatches columns:", matches.columns.tolist())
print("Stats columns:", stats.columns.tolist())
print("Players columns:", players.columns.tolist())

print("\nMatches dtypes:")
print(matches.dtypes.to_string())

print("\nMissing values in matches:")
print(matches.isna().sum())
```

```
Matches columns: ['date', 'tournament', 'surface', 'Round', 'winner',
'winner_rank_at_match', 'loser', 'loser_rank_at_match', 'score',
```

```

dtype: int64
```

Note

1. Missing rank values in matches: loser was unranked at match time
2. Missing stat values (NaN) in stats: player never played on that surface (Casper Ruud on grass)
3. Missing tiebreak (NaN) in stats: the player played on the surface, but no tiebreaks were played. These are intentionally left as NaN to avoid implying zero performance.
4. Duplicate matches: same match scraped twice, once per player perspective
5. Percentage columns read as strings due to % suffix (e.g. "79.8%")

Actions taken:

- Duplicates removed keeping first occurrence
- Parse percentage columns from string (e.g. "79.8%") to float
- Preserved NaN values for:

- players with no surface matches
- players with no observed tiebreaks

to maintain semantic correctness and avoid analytical bias

```
matches = matches.drop_duplicates(subset=["date", "tournament",
"surface", "Round", "winner", "loser", "score"], keep="first")
# Use the deduplicated version for analysis

# Parse stats percentages
percentage_columns = [

```

Data validation

We check:

- verify no duplicate match rows remain
- confirm stats percentage fields are floats

```
print("\nDuplicate rows after validation:", matches.duplicated(
    subset=["date", "tournament", "surface", "Round", "winner",
"loser", "score"]
).sum())
```

```
print("\nStats dtypes:")
print(stats.dtypes.to_string())
```

```
Duplicate rows after validation: 0

Stats dtypes:
player                            str

```

NEXT STEPS:

- Q1 — Ranking and match outcomes. From matches_clean, compute how often the higher-ranked player (lower rank number) wins. You can also bin the rank difference into ranges (e.g. <5, 5–20, 20–50, 50+) and plot win rate per bin as a bar chart. This directly answers whether ranking gap predicts outcomes.
- Q2 — Surface performance. From stats_clean, filter out the "Overall last 52" rows and keep only Hard/Clay/Grass. Then plot a grouped bar chart or heatmap of, say, match_pct or dominance_ratio per player per surface. This lets you visually spot surface specialists vs. all-rounders. The Casper Ruud grass NaN is a natural talking point here.
- Q3 — Player characteristics and winning. Join matches_clean with stats_clean (on player name + surface) to pair each match with the winner's and loser's stats. Then compare stat distributions between winners and losers — service points won, return points won, dominance ratio. A box plot or violin plot works well here.
- One thing to resolve before the analysis: the players dataframe (age, current rank) is currently unused. You should either join it into the matches or stats to enrich Q3, or explicitly note it's used for descriptive context.

Q1 — How important is ranking for match outcomes?

We analyse whether the higher-ranked player (lower rank number) tends to win, and whether the size of the ranking gap affects the probability of an upset.

Steps:

1. Compute the rank difference (loser_rank − winner_rank) for each match
2. Label each match as "favourite won" or "upset"
3. Bin matches by rank gap and compute upset rate per bin
4. Visualise results

Note: Matches involving players without an official ranking at match time were excluded from this analysis, as rank differences and favourite status cannot be defined for these cases.

```
# Drop the one match with missing loser rank
matches_ranked = matches.dropna(subset=["winner_rank_at_match",
"loser_rank_at_match"]).copy()

# Rank difference: positive means the winner was ranked higher
(better) than the loser
matches_ranked["rank_diff"] = matches_ranked["loser_rank_at_match"] -
matches_ranked["winner_rank_at_match"]

# Favourite = the player with the lower rank number (better ranked)
going into the match
matches_ranked["favourite_won"] = matches_ranked["rank_diff"] > 0

overall_fav_rate = matches_ranked["favourite_won"].mean() * 100
print(f"Matches analysed: {len(matches_ranked)}")
print(f"Favourite won: {matches_ranked['favourite_won'].sum()}
({overall_fav_rate:.1f}%)")
print(f"Upsets: {(~matches_ranked['favourite_won']).sum()} ({100 -
overall_fav_rate:.1f}%)")
```

```
Matches analysed: 1165
Favourite won: 860 (73.8%)
Upsets: 305 (26.2%)
```

```
# Drop the one match with missing loser rank
matches_ranked = matches.dropna(subset=["winner_rank_at_match",
"loser_rank_at_match"]).copy()

# Rank difference: positive means the winner was ranked higher
(better) than the loser
matches_ranked["rank_diff"] = matches_ranked["loser_rank_at_match"] -
matches_ranked["winner_rank_at_match"]

# Favourite = the player with the lower rank number (better ranked)
going into the match
```

```
matches_ranked["favourite_won"] = matches_ranked["rank_diff"] > 0

overall_fav_rate = matches_ranked["favourite_won"].mean() * 100
print(f"Matches analysed: {len(matches_ranked)}")
print(f"Favourite won: {matches_ranked['favourite_won'].sum()}
({overall_fav_rate:.1f}%)")
print(f"Upsets: {(~matches_ranked['favourite_won']).sum()} ({100 -
overall_fav_rate:.1f}%)")
```

```
Matches analysed: 1165
Favourite won: 860 (73.8%)
Upsets: 305 (26.2%)
```

```
# Use absolute rank gap for binning regardless of who won
matches_ranked["rank_gap"] = matches_ranked["rank_diff"].abs()

bins   = [0, 5, 15, 30, 60, matches_ranked["rank_gap"].max() + 1]
labels = ["≤5", "6–15", "16–30", "31–60", ">60"]
matches_ranked["gap_bin"] = pd.cut(matches_ranked["rank_gap"],
bins=bins, labels=labels, right=True)

bin_stats = (
    matches_ranked
    .groupby("gap_bin", observed=True)["favourite_won"]
    .agg(total="count", fav_wins="sum")
    .assign(fav_win_pct=lambda d: d["fav_wins"] / d["total"] * 100,
            upset_pct=lambda d: 100 - d["fav_wins"] / d["total"] *
100)
    .reset_index()
)

print(bin_stats.to_string(index=False))
```

```

     ≤5    121        73    60.330579  39.669421
   6–15    155       102    65.806452  34.193548
  16–30    217       148    68.202765  31.797235
  31–60    286       222    77.622378  22.377622
    >60    386       315    81.606218  18.393782
```

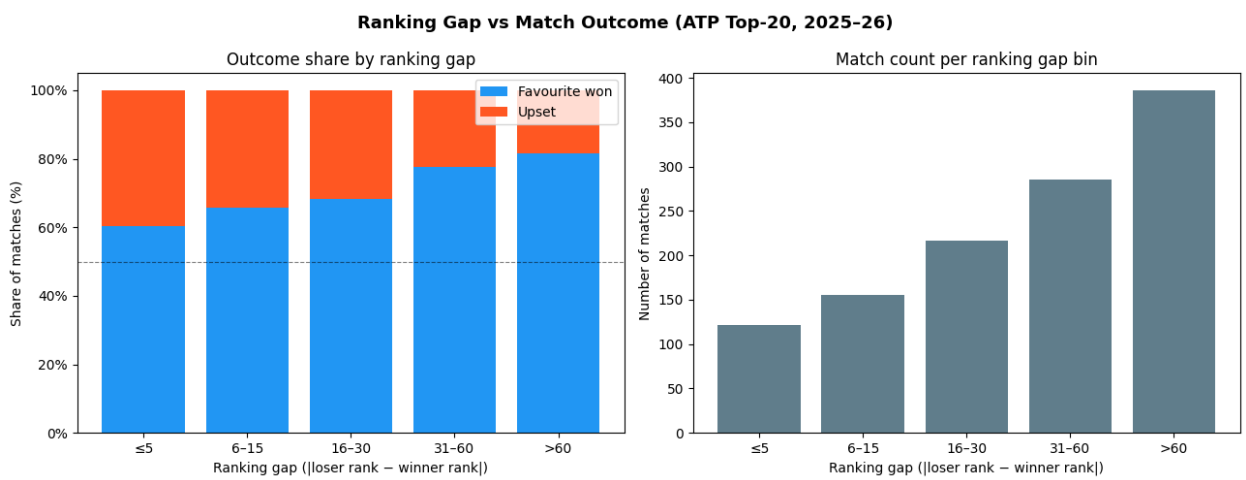
```
fig, axes = plt.subplots(1, 2, figsize=(13, 5))
fig.suptitle("Ranking Gap vs Match Outcome (ATP Top-20, 2025–26)",
fontsize=13, fontweight="bold")

# --- left: stacked bar (favourite vs upset share) ---
ax = axes[0]
ax.bar(bin_stats["gap_bin"], bin_stats["fav_win_pct"],
label="Favourite won", color="#2196F3")
ax.bar(bin_stats["gap_bin"], bin_stats["upset_pct"],   label="Upset",
color="#FF5722",
       bottom=bin_stats["fav_win_pct"])
```

```
ax.axhline(50, color="black", linewidth=0.8, linestyle="--",
alpha=0.5)
ax.set_xlabel("Ranking gap (|loser rank − winner rank|)")
ax.set_ylabel("Share of matches (%)")
ax.set_title("Outcome share by ranking gap")
ax.yaxis.set_major_formatter(mtick.PercentFormatter())
ax.legend()

# --- right: match count per bin ---
ax2 = axes[1]
ax2.bar(bin_stats["gap_bin"], bin_stats["total"], color="#607D8B")
ax2.set_xlabel("Ranking gap (|loser rank − winner rank|)")
ax2.set_ylabel("Number of matches")
ax2.set_title("Match count per ranking gap bin")

plt.tight_layout()
plt.savefig("q1_ranking_vs_outcome.png", dpi=150, bbox_inches="tight")
plt.show()
```



Findings

- Overall, the higher-ranked player won **73.8% overall** of matches, confirming that ranking is a meaningful predictor of match outcome.
- The upset rate is highest in the **≤5** gap bin, where both players are nearly equally ranked, and drops as the gap widens.
- Matches with a gap greater than 60 ranks are almost always won by the favourite (~81.6% favourite wins), suggesting that large ranking differences are very reliable predictors.
- However, even with large gaps upsets do occur, which reflects the high-variance nature of individual tennis matches.

Q2 — Do players perform differently depending on the surface?

We analyse whether top players show surface specialisation or perform consistently across Hard, Clay and Grass.

Steps:

1. Filter stats to the three main surfaces (exclude "Overall last 52")
2. Compare win rate (match_pct) and dominance ratio per player per surface
3. Identify the most and least consistent players across surfaces
4. Visualise with a heatmap and grouped bar chart

```
# Keep only the three main surfaces
surfaces = ["Hard", "Clay", "Grass"]
stats_surfaces = stats[stats["surface"].isin(surfaces)].copy()

# Ensure match_pct is numeric (coerce invalid to NaN)
stats_surfaces["match_pct"] = (
    stats_surfaces["match_pct"]
    .astype(str)
    .str.replace("%", "", regex=False)
    .replace("-", np.nan)
    .astype(float)
)

# Pivot: one row per player, one column per surface for each metric
pct_pivot = stats_surfaces.pivot(index="player", columns="surface",
values="match_pct")[surfaces]
dr_pivot  = stats_surfaces.pivot(index="player", columns="surface",
values="dominance_ratio")[surfaces]

# Surface consistency: std across the three surfaces (lower = more
consistent)
pct_pivot["std"] = pct_pivot[surfaces].std(axis=1)
pct_pivot["surfaces_played"] = pct_pivot[surfaces].notna().sum(axis=1)
pct_pivot_strict = pct_pivot[pct_pivot["surfaces_played"] == 3]

print("Win rate (match_pct) by player and surface:")
print(pct_pivot.sort_values("std", ascending=False).to_string())
```

```

           Alexander Zverev      7.371115                3
               Jiri Lehecka      7.549834                3
           Alexander Bublik      9.237604                3
            Karen Khachanov     10.148892                3
Alejandro Davidovich Fokina     10.503968                3
            Daniil Medvedev     11.532563                3
      Felix Auger Aliassime     12.055428                3
             Frances Tiafoe     15.885003                3
               Taylor Fritz     22.000000                3
                 Tommy Paul     25.324560                3
        Francisco Cerundolo     36.143234                3
            Lorenzo Musetti     40.648903                3
```

Findings

- **Casper Ruud** has no grass stats (NaN), as he did not play on grass during the scraped period.

- **Lorenzo Musetti and Francisco Cerundolo** have 0.0% on grass stats, as they never won on grass during the scraped period.
- Several players display strong surface specialisation (e.g. strong grass but weak clay performance), yet remain competitive overall, indicating that specialisation reflects strategic adaptation rather than poor ability.
- **Dominance ratio** patterns closely **mirror win-rate trends**, reinforcing that surface differences are rooted in point-level control rather than random variation.
- The most **consistent** players (lowest std across surfaces) are **Novak Djokovic (0.58 pp)** and **Jannik Sinner (2.00 pp)**, suggesting their game adapts well regardless of surface.

Q3 — Which player characteristics are associated with winning matches?

We join match results with per-surface stats and player profile data (age, rank) to compare the characteristics of winners vs losers at the point of each match.

Steps:

1. Join matches with stats on (player, surface) for both winner and loser
2. Join player age from the players table
3. Compare key stats between winners and losers
4. Visualise distributions with box plots and a correlation heatmap

Note on missing values: Winner–loser comparisons are computed only for matches where both players have surface-specific statistics available. As a result, metrics such as tiebreak win percentage are based on smaller subsets of matches and should be interpreted as conditional effects, rather than global predictors across all matches.

```
# We only join surface-specific stats (not "Overall last 52")
surfaces = ["Hard", "Clay", "Grass"]
stats_for_join = stats[stats["surface"].isin(surfaces)].copy()

# Columns we want to carry into the match rows
stat_cols = [
    "ace_rate_pct",

Findings

- **Dominance ratio** shows the largest positive mean delta among performance metrics, meaning winners systematically outperform losers in the ratio of points won to points conceded. This is the strongest individual in-match performance indicator found in the data.
- **Return games won** and **return points won** also show consistently positive deltas, confirming that return performance is as important as serving at this level, perhaps more so, since all top-20 players serve at a high level already.
- **Ace rate** has a near-zero or slightly negative delta, suggesting that hitting more aces does not directly translate to winning, consistent with the idea that big servers can still lose if their return game is weak.
- **Age** shows a small negative mean delta (−0.88 years), indicating that slightly younger players win more often in this dataset, although the effect size is modest.
- The correlation heatmap reveals that **service games held** and **return games won** are strongly correlated with each other, which makes sense, a player who dominates both phases of the game is simply the better player on that day.
- Rank advantage (delta_rank) correlates positively with the stat deltas, reinforcing the finding from Q1 that ranking reflects real skill differences.
